

ChronicleInk

Product Architecture & Technical Specifications

Version 1.0 (Core Engine)

1. Executive Summary

ChronicleInk v1.0 is engineered as a lightweight, localized desktop environment designed explicitly for multi-media storytellers, comic illustrators, and independent film directors. The core directive of Version 1.0 is to eliminate structural friction when translating raw textual narratives into visual-ready prompts, allowing creative professionals to establish rapid pre-visualization workflows without technical overhead.

2. Functional Architecture & Components

The system utilizes an uncoupled local architecture divided into three discrete functional spaces, prioritizing fast processing times and absolute privacy of intellectual property.

2.1 Scene Parsing Engine (SPE)

The SPE features an optimized Markdown text editor capable of executing real-time lexical parsing. By evaluating standardized script markup formats, it flags and extracts metadata parameters instantaneously:

- **Scene Identifiers:** Automated recognition of standard prefixes (e.g., INT., EXT.).
- **Entity Extraction:** Tracks character occurrences across sequential scenes to map continuity requirements automatically.
- **Action Aggregation:** Separates contextual environmental descriptions from dialog sequences to build clean visual contexts.

2.2 Visual Prompt Generator (VPG)

The VPG translates natural language action blocks into structural prompt formats suitable for consumption by external generative neural systems. Rather than basic text duplication, the engine wraps action items in compositional wrappers (e.g., establishing medium shots, tracking depth of field parameters, and mapping environmental lighting states based on scene text flags).

2.3 Local Asset Binder (LAB)

Operating completely within local system memory, the LAB functions as an interactive workspace anchor. Creators can dynamically bin mood board elements, vector layouts, reference assets, and custom character sheets alongside parsed textual scenes. This binds visual source inputs directly with corresponding text tracks without requiring network persistence.

3. Technical Environment & Portability

Version 1.0 operates entirely client-side. Storage configurations lean on standardized local Markdown structures (`.md`), enabling clean structural portability across various external document editing environments. All parsing loops are compiled down to optimize native thread execution times, protecting system overhead during heavy production cycles.
